Warshel , PNAS (1978)

- The secret of Enzyme catalysis is electrostatic preorganization

Reaction in water

Spend a large amount of energy rotating the water molecules

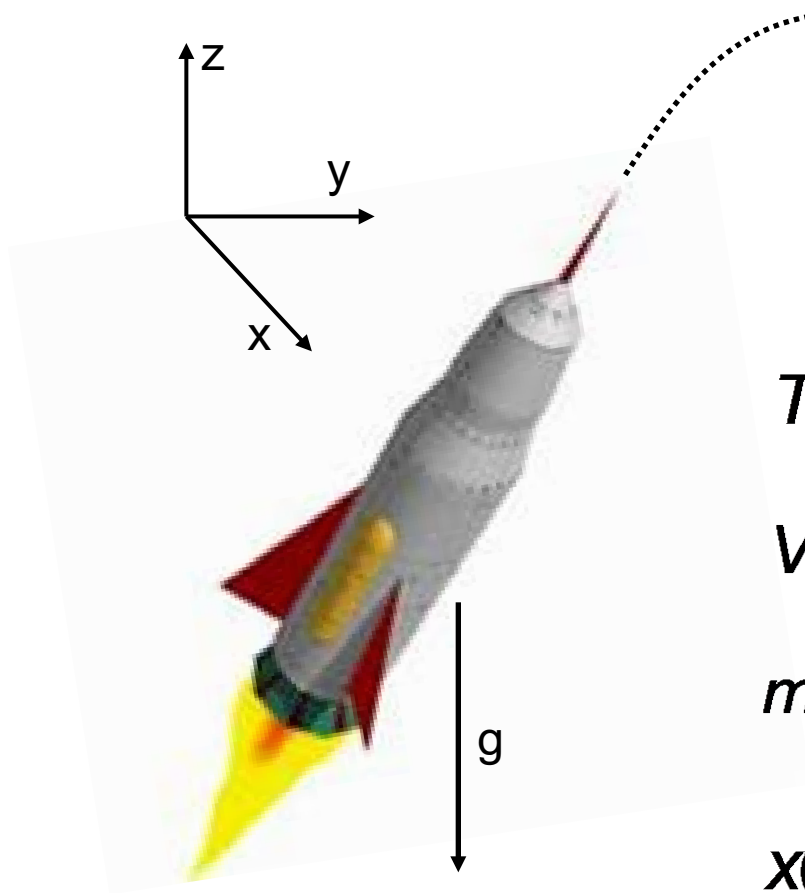

Reaction in protein

The protein polar groups and charges are already pointing in the correct direction

Bridging time scales and length scales

For short time scales can use direct MD simulations to determine the exact time dependence on an atomistic level

$$T = \frac{1}{2} m (\dot{x}^2 + \dot{y}^2 + \dot{z}^2)$$

$$V = mgz$$

$$m\ddot{z} = -\frac{\partial V}{\partial z} = -mg$$

$$x(t) = x_0 + \dot{x}_0 t$$

$$z(t) = z_0 + \dot{z}_0 t - \frac{1}{2} g t^2$$

What about reproducing the structural changes and their time dependence and long time dynamics

Needs Free Energy landscape and efficient approach

Coarse Grained (CG) approaches

Very Early CG

Computer Simulation of Protein Folding

Michael Levitt and Arieh Warshel, *Nature* (1975) 253, 694-698

Fig. 1 Relationship between the simplified model of protein structure introduced here and the real all-atom structure of proteins. The two reference points for each residue in the simplified model correspond to the centroid of the side chain and the C^α . Each residue is only allowed one degree of freedom: the torsion angle α between the 4 successive C^α s of residues ($i-1$, i , $i+1$, $i+2$). All the side chains of a given type have the same simplified geometry. The bond lengths, bond angles, and torsion angles used to define the geometry of the simplified molecule were taken as the average values found in eight protein conformations, though they could just as well have been taken from amino-acid model compounds.

Improved Coarse Grained Model

PROTEINS , 78, 1212–1227 (2010)
Ann Rev Phys Chem 62, 41-64 (2011)

Now focused on better treatment of electrostatics free energy

Mainly self energy (solvation) and charge-charge interaction

$$\Delta G_{self} = \sum_i \left(U_{self}^{np} (N_i^{np}) + U_{self}^p (N_i^p) + U_{self}^{mem} (N_i^{mem}) \right)$$

F₁F₀-ATP synthase – The smallest rotary motor

The 1997 Nobel Prize in Chemistry

How the rotating γ -subunit imposes conformational states on a β -subunit required for substrate binding, ATP formation and ATP release.

© Medical Research Council

F₁F₀ are two coupled rotary motors; an ATPase and an ion-pump

In presence of right ion-gradient F₀ transports ion across the membrane and F₁ synthesizes ATP

In the opposite direction ATP hydrolysis occurs in F₁, while F₀ acts as an ion-pump

Mechano-Chemical Coupling between the central stalk and the catalytic dimers in F_1

Each 120° rotation of the Stalk broken in 80° and 40° steps by the Catalytic Dwell

Yasuda, R. et al., Nature, 2001.

The CG electrostatic free energy for the 360° rotation of central stalk and catalytic subunit conformation

S. Mukherjee and A. Warshel, *Proc. Natl. Acad. Sci. USA*, 108, 20550–20555 (2011)

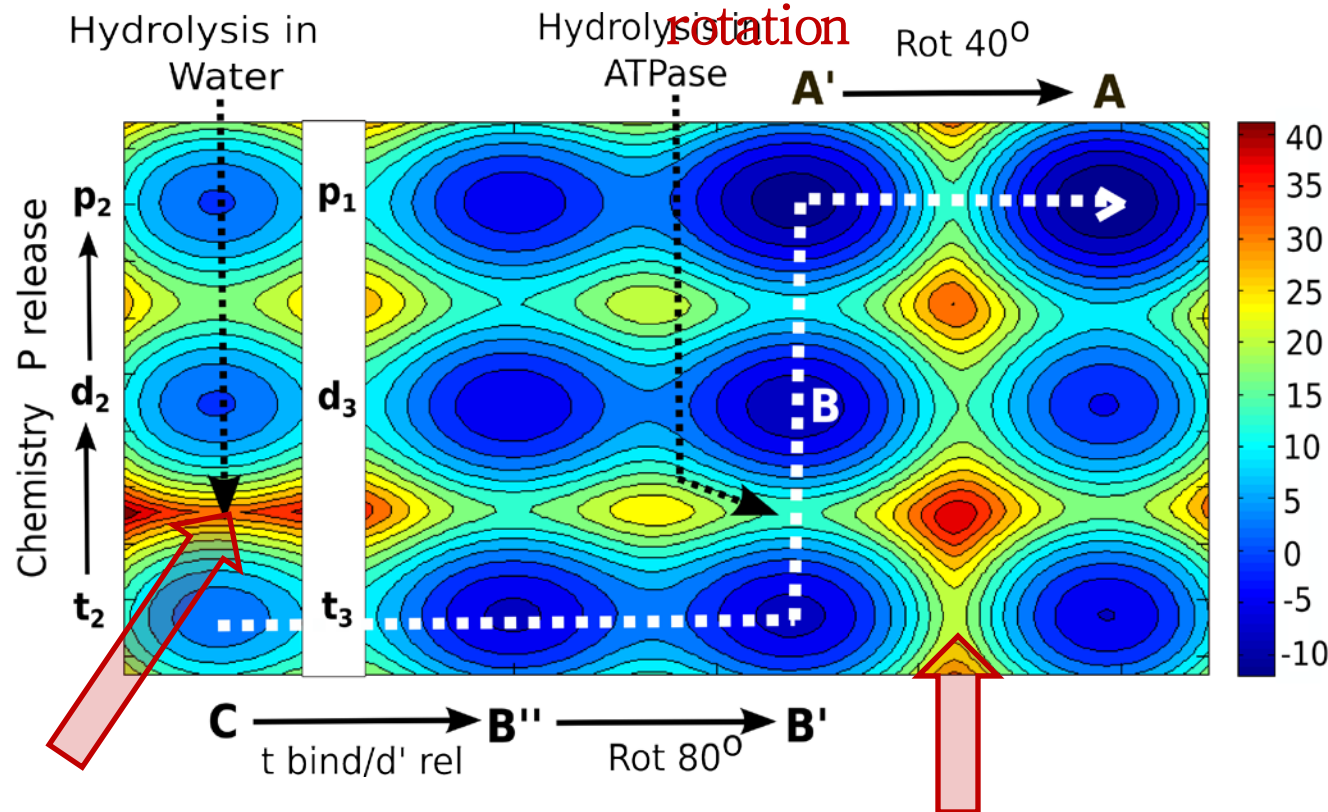

The least energy path clearly shows the 80° /40° substeps.

The 80° rotation has small electrostatic barrier.

The 40° rotation and conformation change of catalytic subunits has

Simplified surface of F_1 -ATPase function shows the coupling of ATP hydrolysis with central stalk rotation

The functional surface reveals why catalysis occurs after 80°

ATP hydrolysis in water has very high barrier and will need months to occur

High barrier of 40° rotation and catalytic subunit changes bias the system towards ATP hydrolysis

F1F0-ATP synthase – The smallest rotary motor

F1F0 are two coupled ATPase and ion-pump

Consists of a rotary motor and a stator portion

In presence of right ion-gradient across the membrane ATP synthesis occurs in the F1

In the opposite direction ATP hydrolysis occurs while the F0 acts as an ion-pump

What drives unidirectional walking motion of myosin V on actin filaments

Almost no backsteps as myosin V walks over actin filament

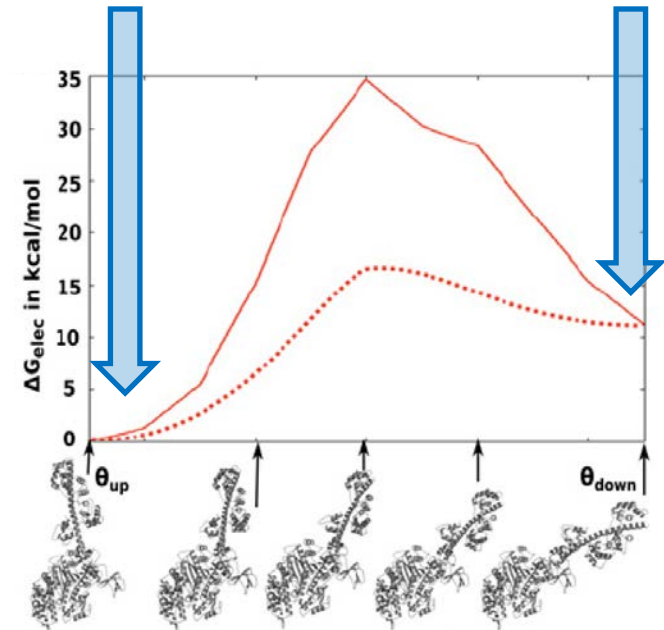

It is hard to understand unidirectional movement, even in our daily life !!!

CG energetics of a single leg as it bends (changes conformation)
